Analyzing Video Game Sales

Summary

A few sentences describing the inferential question(s), the method used and the most important results.

Introduction

A more in-depth introduction to the inferential question(s) of interest.

The video game industry has been growing consistently during the last two decades, and in 2017 it was worth more than 78 billion USD worldwide. Video game software sales account for around 80% of total revenue. There are several factors that influence whether a video game will be successful or not, such as the developer studio, the critics rating, the user rating, among others. I will build a model to analyze what factors can help us determine how successful will a video game be in terms of global sales.

I analyzed a total of 4195 video game software releases across the world by 50 different developers. I built a hierarchical linear model on a logarithmic transformation of the global sales, with random slopes by developer, using a manual stepwise selection process using BIC and conditional R-squared as selection criteria. The variables on the final model were found to be significant in predicting the global sales for a video game.

The goal of this project is to find what are the most significant predictors for a video games success, measured as the number of sales around the world. I use a hierarchical linear regression model to explain the number of sales a particular videogame has. Considering that the developing studio plays a major role on a customer's decision to buy a new game, and due to the fact that accounting for every single studio included in the dataset (444 total) would make the interpretation too complicated, I used a random sample of 50 developers and built an appropriate hierarchical model with random intercepts effects for each one of them.

Data

The data was obtained from Kaggle (<https://www.kaggle.com/rush4ratio/video-game-sales-with-ratings>). It contains data from video games with 100,000 or more global sales from 1976 to 2016. The data contains 16719 rows with the following columns:

- *name* (categorical): Name of the video game
- *platform* (categorical): PPlatform or console for which the video game was released
- *year_of_release* (categorical): Year of first release
- *genre* (categorical): Genre of the video game
- *publisher* (categorical): Publishing company
- *na_sales* (numerical): Units sold in North America
- *eu_sales* (numerical): Units sold in Europe
- *jp_sales* (numerical): Units sold in Japan
- *other_sales* (numerical): Units sold in the rest of the world
- *global_sales* (numerical): Total units sold worldwide
- *critic_score* (numerical): Average score (from 0 to 100) according to critics from other media aggregated by Metacritic
- *critic_count* (numerical): Number of critics taken into account for the Metacritic critic score

- *user_score* (numerical): Average score (from 0 to 100) according to Metacritic users
- *user_count* (numerical): Number of user scores on Metacritic
- *developer* (categorical): Video game developing company
- *rating* (categorical): Video game rating according to the ESRB that indicates the appropriate audience

Around half of the rows in the dataset have missing values. First of all, I filtered out every video game release before 2000 since it seemed that for older releases there was more missing data and this report is only concerned with more recent releases. After observing the rest of the rows, the missing data seemed to be at random, so I decided to use only the 6951 rows with complete data.

Since the categorical variables have many levels (See Appendix 1.1 for a summary of the dataset *vgsales*) and in order to center the numerical variables to avoid multicollinearity issues, I created the following additional columns:

- *critic_score_c* (numerical): Values of *critic_score* minus the column's mean value
- *critic_count_c* (numerical): Values of *critic_count* minus the column's mean value
- *user_score_c* (numerical): Values of *user_score* minus the column's mean value
- *user_count_c* (numerical): Values of *user_count* minus the column's mean value
- *platform_company* (categorical): Company that manufactures the video game's platform
 - 'Nintendo' when *platform* is '3DS', 'DS', 'GB', 'GBA', 'GC', 'N64', 'Wii', or 'WiiU'
 - 'Sega' when *platform* is 'DC'
 - 'PC' when *platform* is 'PC'
 - 'Microsoft' when *platform* is 'X360', 'XB', or 'XOne'
 - 'Sony' when *platform* is 'PS', 'PS2', 'PS3', 'PS4', 'PSP', or 'PSV'
- *rating_everyone* (binary): Indicates if there is not an age restriction for the video game release
 - '1' when *rating* is 'E'
 - '0' when *rating* is not 'E'

To consider the variable *publisher* into the model, I took a random sample of 50 different publishing companies from the dataset and built a sample dataset to work with. I observed at the distribution of the response variable *global_sales* and noticed that its distribution is not normal. After applying a logarithmic transformation, the distribution is normal, so I added the following column to the dataset:

- *log_global_sales*: Logarithmic transformation of *global_sales*

A summary of the data variables being analyzed can be found in Appendix 1.1.

For the Exploratory Data Analysis, I plotted every relevant variable versus the response variable *log_global_sales*. All of the categorical variables seemed to have different means for the response variable on at least two levels, and the numerical variables seemed to have a positive effect on the response variable. I observed at some interactions between categorical variables (*platform_company:rating_everyone*, *platform_company:genre*, and *genre:rating_everyone*) and since the distributions seemed to vary I took them into account during the model selection. (For a full EDA, see Appendix 1.2).

Model

A detailed description of the model used, how you selected the model, how you selected the variables, model assessment, model validation, and presentation of the model results. What are your overall conclusions in context of the inferential problem(s)?

In order to obtain a final model for the response variable *log_global_sales* various methods for model selection were tested and interactions between predictors were considered as part of the full model. Since the publishing companies in the sample dataset are a sample of the total publishers available, I included random intercept effects for *publisher* in the final model. The categorical and numerical variables (except for *na_sales*, *eu_sales*, *jp_sales*, and *other_sales*, since their sum is exactly equal to *global_sales*) were taken into account for the model selection as predictors. The interaction terms *platform_company:genre*, *platform_company:rating_everyone*, and *genre:rating_everyone* were considered too.

The final model was selected with a manual stepwise approach in R, using AIC and the conditional R_{GLMM}-squared (conditional R-squared) from the MuMIn package, which is described as “a variance explained by the entire model, including both fixed and random effects” in *r.squaredGLMM* function documentation. The final model’s conditional R-squared is 0.4928372, meaning almost half of the data’s variance is explained by the model.

All of the VIF values of the model predictors are below 5 with the exception of *rating_everyone* (See Appendix 1.3. for each individual VIF value). I decided to keep the variable in the model because the interactions between *rating_everyone* and the categorical variables improve the model significantly. For the most part, the model does not show any serious multicollinearity issues. The model assumptions of linearity, independence, and equal variance seem to be met. The normality assumptions may be a reason to worry about since the Q-Q shows tails on both sides. (See Appendix 1.4.)

The variables *platform*, *genre*, *critic_score_c*, *critic_count_c*, *user_count_c*, as well as the interactions *platform:rating_everyone* and *genre:rating_everyone* were found to be significant. The variable *rating_everyone* was added to the model because its interactions had significant levels and improved the model considerably. With an AIC value of 12114, the final model has the following formula:

$$\begin{aligned}
 \log_global_sales_{i,j} = & \beta_{(\text{Intercept})} + \gamma_{(\text{Intercept}),j} + \sum_{p \in P} \beta_p (platform_company_p)_{i,j} + \sum_{g \in G} \beta_g (genre_g)_{i,j} \\
 & + \beta_{rating_everyone} rating_everyone_{i,j} + \beta_{critic_score_c} critic_score_c_{i,j} + \beta_{critic_count_c} critic_count_c_{i,j} \\
 & + \beta_{user_count_c} user_count_c_{i,j} + \sum_{p \in P} \beta_{p,rating_everyone} (platform_company_p)_{i,j} rating_everyone_{i,j} \\
 & + \sum_{g \in G} \beta_{g,rating_everyone} (genre_g)_{i,j} rating_everyone_{i,j} + \epsilon_{i,j};
 \end{aligned}$$

Where:

$j \in \{\text{Nintendo, 'Microsoft Game Studios', 'Sony Computer Entertainment', Activision, Ubisoft, 'Electronic Arts', 'Konami Digital Entertainment', LucasArts, Atari, 'Namco Bandai Games', Sega, 'Acclaim Entertainment', 'Midway Games', 'Crave Entertainment', Codemasters, 'Marvelous Entertainment', Rondome-
dia, 'Midas Interactive Entertainment', 'Tetris Online', Screenlife, 3DO, 'Home Entertainment Suppliers', 'Indie Games', 'PopCap Games', 'Gathering of Developers', 'Oxygen Interactive', 'Milestone S.r.l.', Agatec, 'XS Games', 'Compile Heart', 'Rebellion Developments', 'Media Rings', 'Yacht Club Games', Enterbrain, Microids, Ackkstudios, 'Little Orbit', 'Reef Entertainment', 'Kool Kizz', '2D Boy', 'DHM Interactive', 'Flashpoint Games', 'Iceberg Interactive', 'Mamba Games', 'bitComposer Games', 'Crimson Cow', 'FuRyu Corporation', 'Blue Byte', 'CDV Software Entertainment', 'Lighthouse Interactive'}\}$

$P = \{\text{Nintendo, PC, Sega, Sony}\}$

$G = \{\text{Adventure, Fighting, Misc, Platform, Puzzle, Racing, Role-Playing, Shooter, Simulation, Sports, Strategy}\}$

$$\epsilon_{i,j} \sim N(0, \sigma^2) \quad \text{and} \quad \gamma_{(\text{Intercept}),j} \sim N\left(0, \tau_{(\text{Intercept})}^2\right)$$

The final model's fixed coefficients have the following values for every β coefficient:

Table 1: Model's Fixed Coefficients

The random intercept effects by publisher or $\gamma_{(\text{Intercept})}$ random effects are shown in the following plot (See Appendix 1.5. for a table with the point estimates):

Conclusions

In this section, you should present the importance of your findings, and describe any limitations of the study. You can also address future work here if there are extensions of your analysis you find interesting, especially those that may address some of the limitations already mentioned.

Voting tendency of different demographic groups could be analyzed from the model we built. Baselines of our model are Age 18 - 25, Democratic Party, Female, Asian, and Hispanic/Latino and we could see the following interesting facts.

- Most of variables are significant.
- All county random intercept effects are significant (except for Jackson), which means the odds of voting differed by county in 2016.
- Except mixed race, most of races are less likely vote as compared to the baseline.
- People aged above 40 are approximately 150% more likely to vote than younger people.
- Libertarians are 75% more likely to vote than other parties although they only make a small fraction of the population
- Males belonging to the Republican Party, Libertarian Party or even if they are Unaffiliated are more likely to vote as compared to the baseline. But, overall males are 23% less likely to vote as compared to overall females.
- The Male supporting Democrats are the group that bring the odds down.

Through the multi-level logistic model from dataset from the North Carolina State Board of Elections (NCSBE), we could reveal the voting tendency of different demographic groups in North Carolina in 2016 and predict the turnout rate of each subgroup. From the analysis, we could find that age, party, race, sex, ethnic, county, etc., are significant factors to decide their tendency of voting.

Although, we could predict turnout rate of voting and voter's tendency, categorical age and unidentified gender, race, ethnic would be clarified to get more precise results.
